Outline

- ▶ Background
- ▶ MPLS: Fundamentals
- ▶ MPLS: Terminology
- ▶ GMPLS
- ▶ GMPLS: Recovery techniques
- ▶ Summary
- ▶ Resources

Background

- ▶ What is MPLS?
 - ▶ Mechanism that directs data from one network node to the next based on on path labels rather than network addresses.
 - ▶ with such mechanism, we avoid lookups in a routing table
 - ▶ MPLS switches packets (IP packets) instead of routing packets to transport the data
- ▶ Why MPLS?
 - ▶ Provide a highly scalable mechanism that was topology driven rather than flow driven
 - ▶ Load balance traffic to utilize network bandwidth efficiently
 - ▶ Allow core routers/networking devices to switch packets based on a simplified header
 - ▶ Remove the complexity and overhead of network managements (Assemble and reassemble IP packets)

MPLS was conceived, why?

- ▶ The shortest path routing protocols like IS-IS and OSPF
 - ▶ Did not take capacity characteristics into account while making the routing decisions
 - ▶ The outcome is, segmentation over the network which leads to congestion, while others remain under-utilized.
- ▶ MPLS reduces the complexity and redundancies by adding new network functionalities.

MPLS Fundamentals

- ▶ Main idea:
 - ▶ attach a short fixed-length label to packets at the ingress to an MPLS domain
 - ▶ the labels are used to make the forwarding decisions.
- ▶ MPLS consists of a forwarding and a control plane.
Though they are decoupled and independent from each other.
- ▶ Supports explicit routed path.
- ▶ Provides Quality of Service (QoS) if it is implemented with Diff-Serv and Constraint-based routing.

Diff-Serv and Constraint-based routing

- ▶ Differentiated Services
 - ▶ A network architecture for classifying and managing network traffic and provide QoS on modern IP networks.
 - ▶ it is used to provide low-latency to critical network traffic. (Media, VOIP).
- ▶ Constraint-based routing
 - ▶ It is a routing technique where resource availability and traffic characterization are taken into account.

MPLS Fundamentals

Fig. 2. Conceptual view of MPLS control plane and forwarding plane.

MPLS Fundamentals: Control Plane

MPLS Fundamentals: Forwarding Plane

MPLS architecture

MPLS: Terminology

- ▶ FEC (Forwarding Equivalence Class)
 - ▶ Group of IP packets which are forwarded in the same manner (e.g. over the same path, with the same priority and the same label)
- ▶ Label
 - ▶ Short fixed length identifier which is used to identify a FEC
- ▶ Label Swapping
 - ▶ Looking up the oncoming label to determine the outgoing label, encapsulation and port
- ▶ Label switched path (LSP)
 - ▶ Path through one or more LSR for a particular FEC
- ▶ Label switching router (LSR)
 - ▶ an MPLS capable router

Advantages?

Disadvantages of MPLS

- ▶ What is GMPLS?
 - ▶ a protocol suite extending MPLS to manage further classes of interfaces and switching technologies other than packet interfaces and switching, such as time division multiplex, layer-2 switch, wavelength switch and fiber-switch.

GMPLS

- ▶ GMPLS is an extended form of MPLS and some of these improvements are:
 - ▶ RSVP-TE
 - ▶ OSPF and IS-IS
 - ▶ New link-management protocol
 - ▶ Bi-directional LSP setup
 - ▶ Reduce latency
 - ▶ Less control overhead
 - ▶ Route selection is simpler
 - ▶ Cleaner interface
- ▶ MPLS emphasizes the separation of control plane and network plane
- ▶ GMPLS extends this separation and allows the control plane to be physically diverse from the associated data plane

GMPLS: Hierarchical LSP

Summary

- ▶ MPLS
- ▶ GMPLS
